What's in iOS?

Media

Core Audio	JPEG, PNG, TIFF
OpenAL	PDF
Audio Mixing	Quartz (2D)
Audio Recording	Core Animation
Video Playback	OpenGL ES

- Cocoa Touch = UI Framework
  = abstraction layer of iOS
  = based on Mac OS X Cocoa API
  = MVC

- Cocoa Touch main frameworks - Foundation (NS)
  - UIKit (UI)

Platform Components

- Tools

Xcode 5

Instruments

- Language

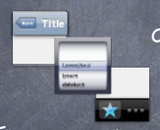
```
[display setTextColor:[UIColor blackColor]];
```

- Frameworks

Foundation

Core Data

Map Kit

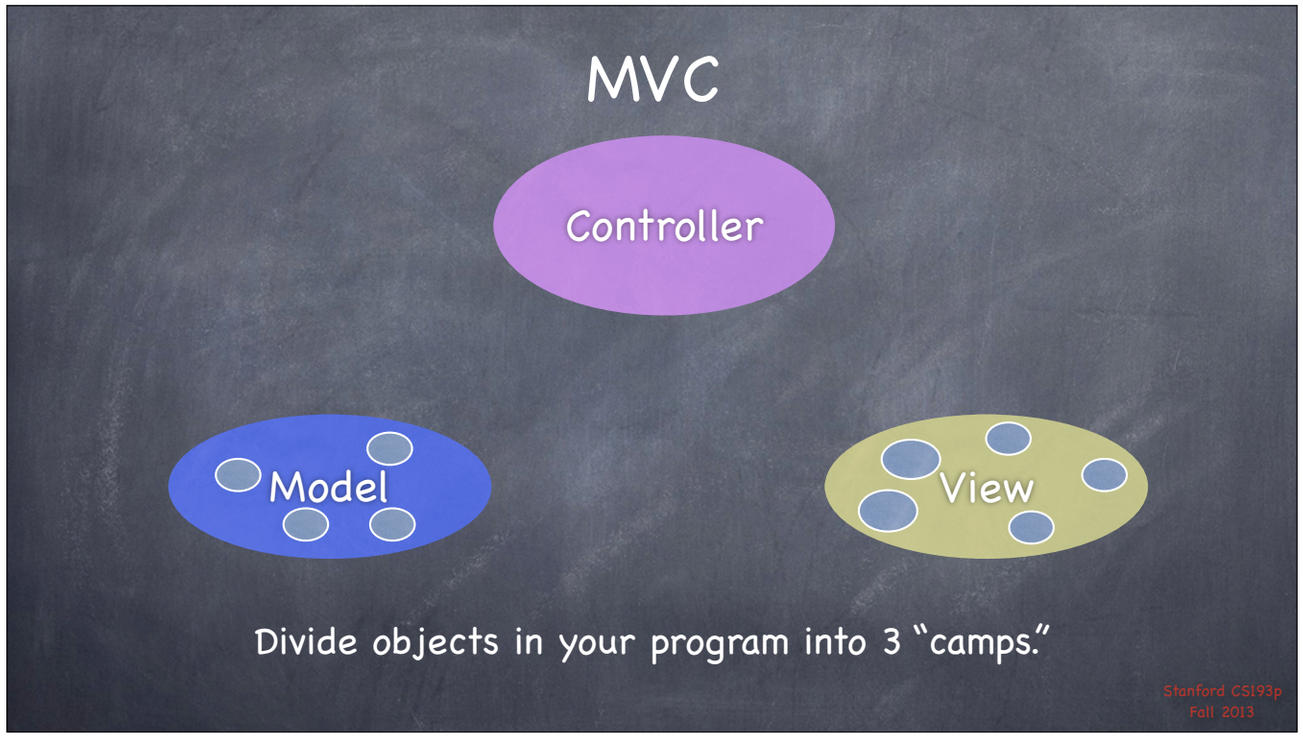


UIKit

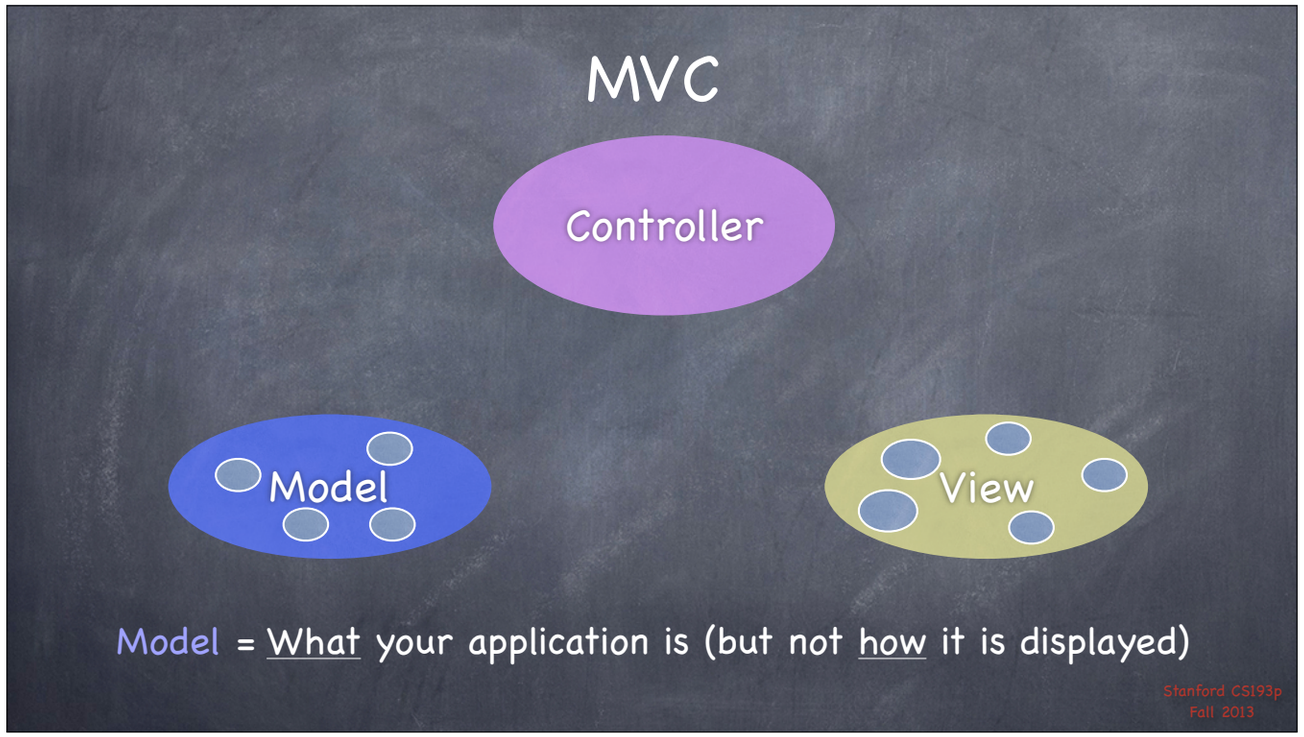
Core Motion

- Design Strategies

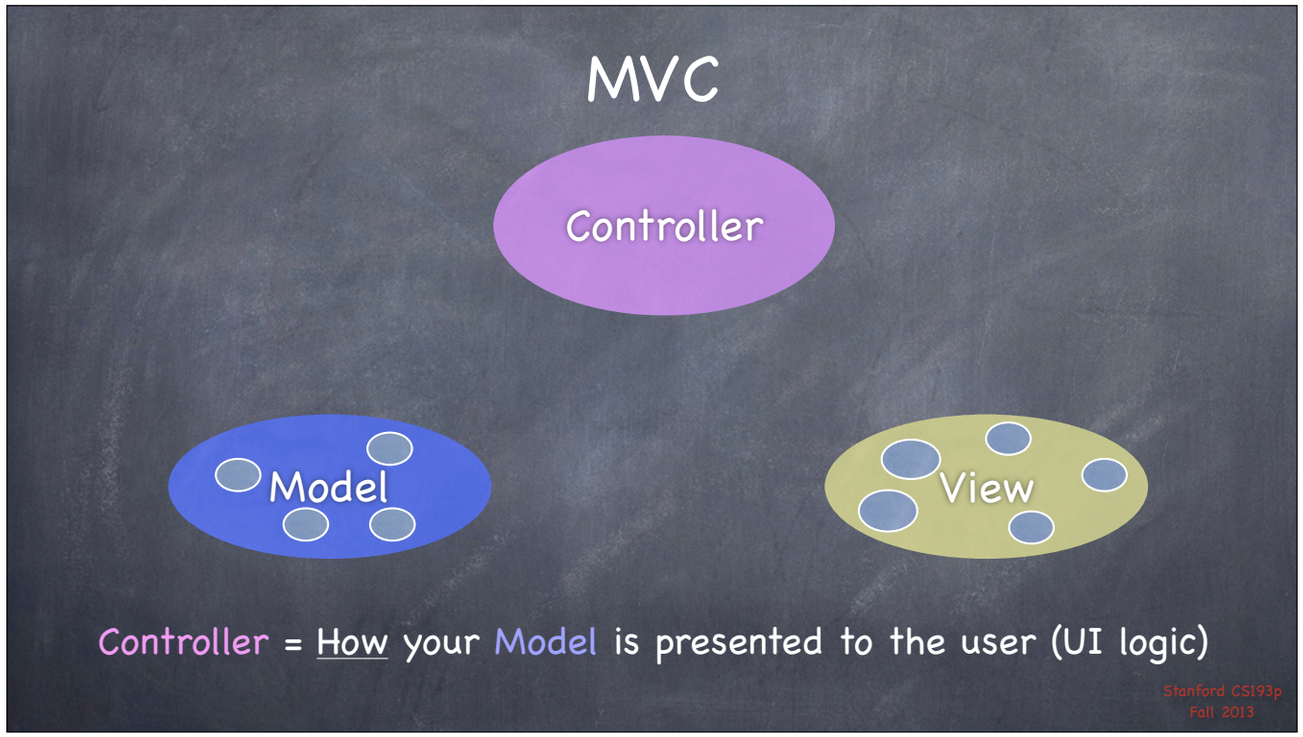
MVC



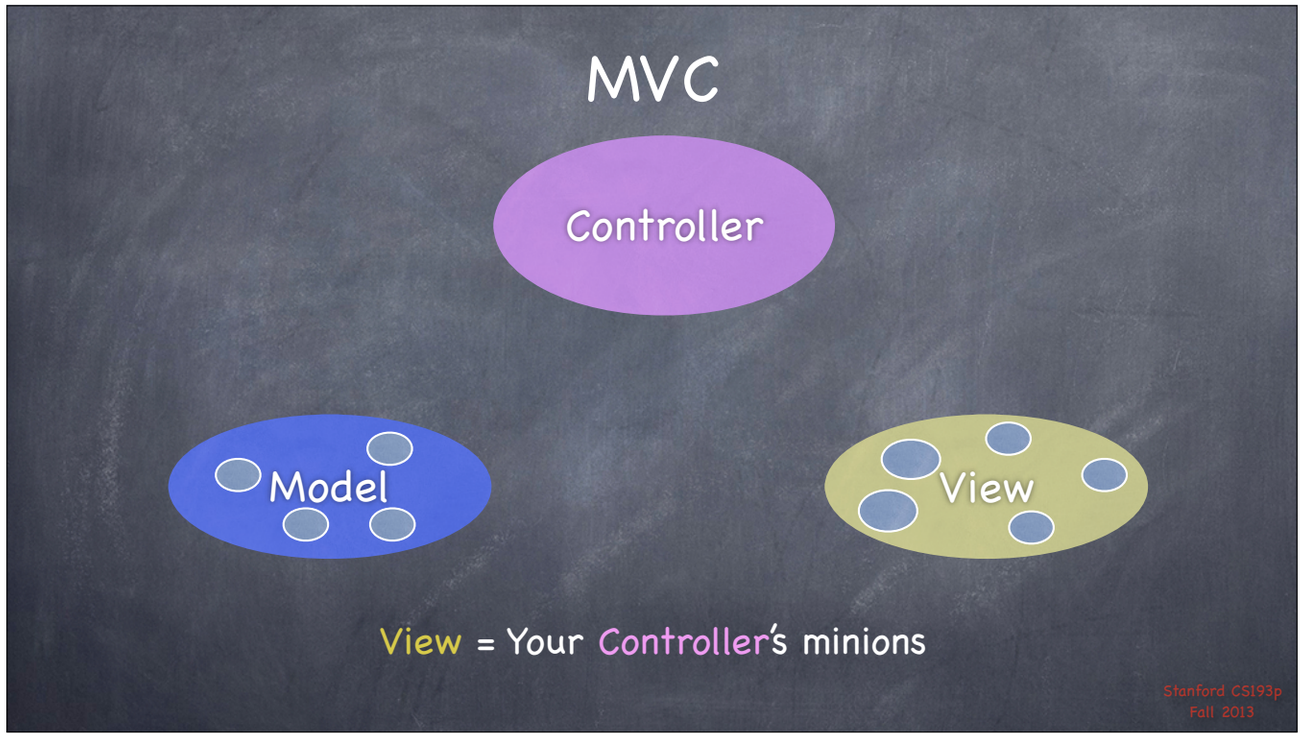
- MVC = Design pattern
- Advantages – reusable code (new views without having to change the model)
  – responsibilities



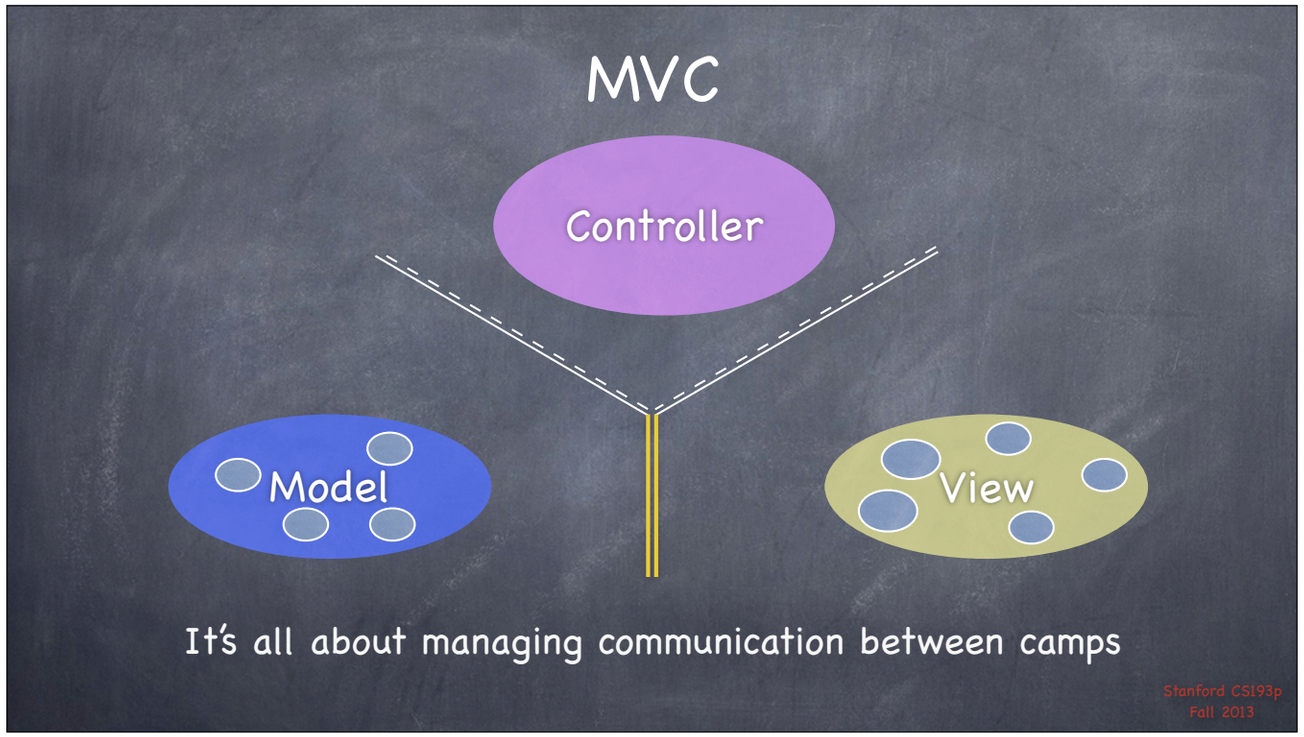
- E.G.- Blog&Co: BlogPost has a title, URL, author, etc.
    - NaLo: Draw has a drawDate, resultNumbers, etc.



- Application logic
- Control flow

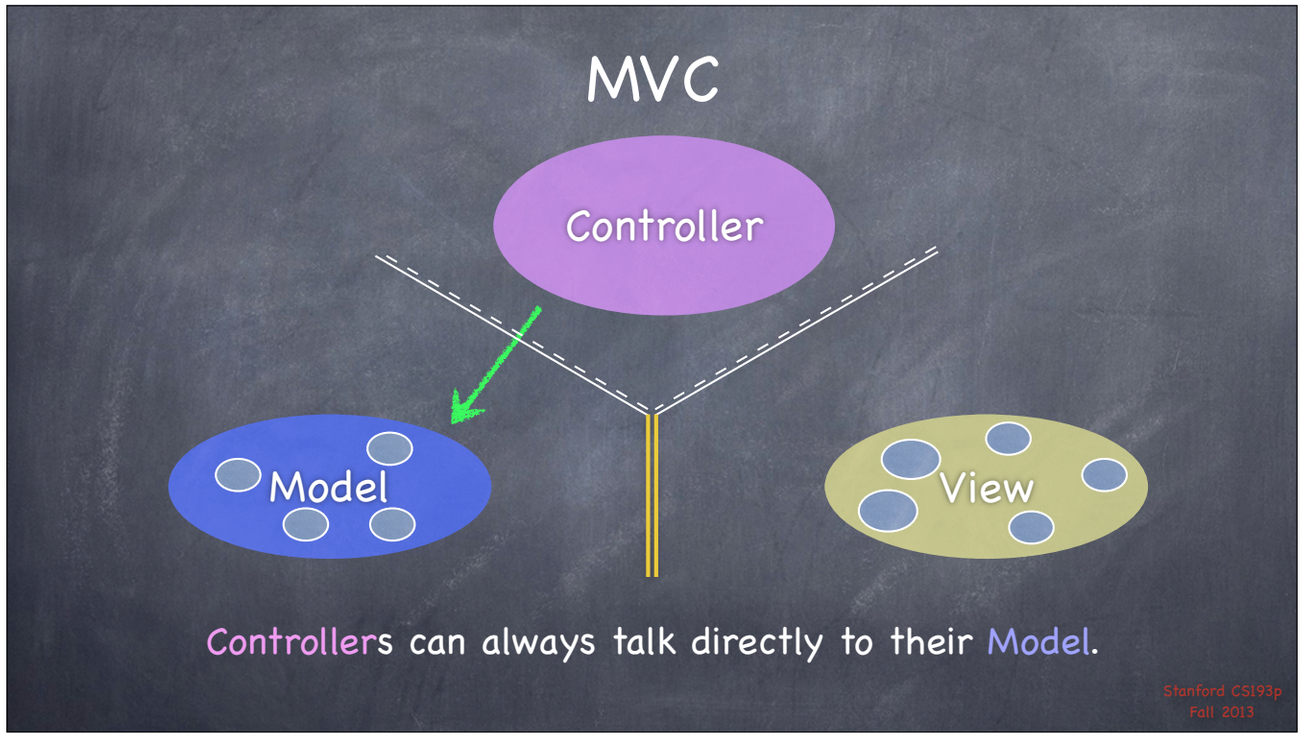


- Display and display only
- Views should never hold models



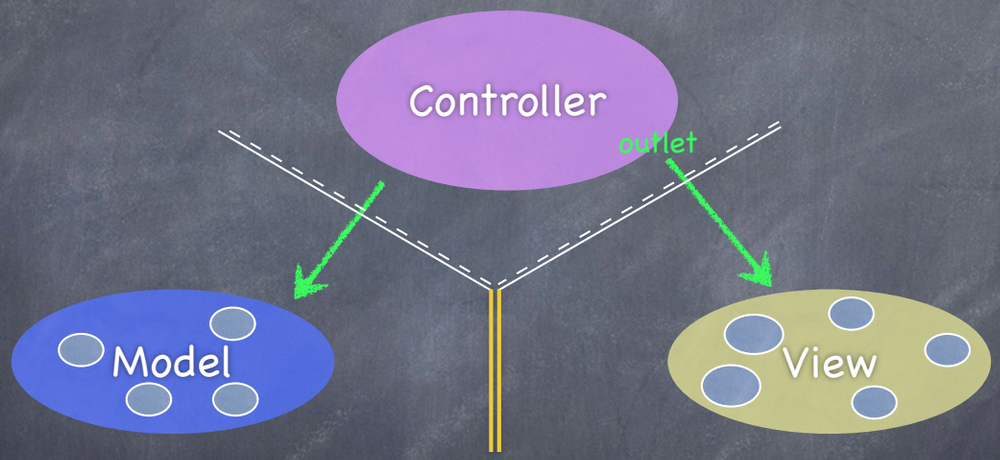
"Verdeel en heers"

- Controller knows model & view
- View knows model
- Model knows nothing



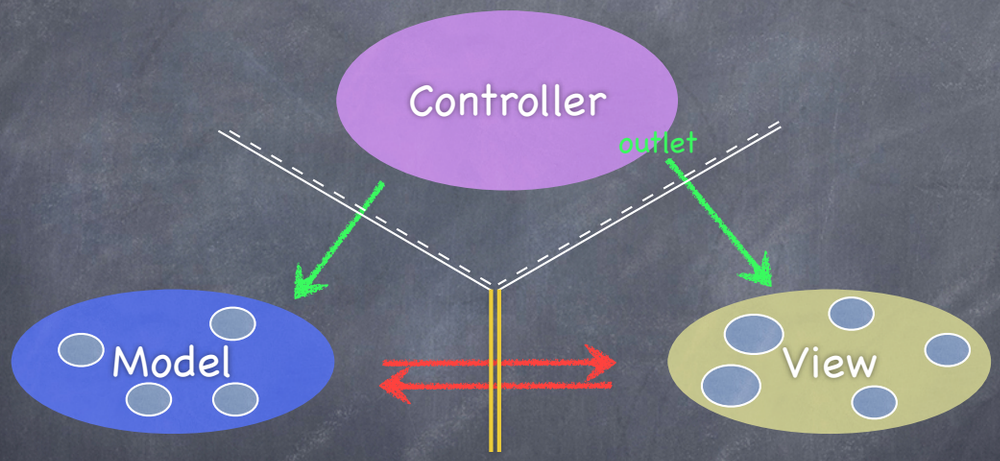
MVC
Controller
Model
View
Controllers can always talk directly to their Model.
Stanford CS193p
Fall 2013

MVC

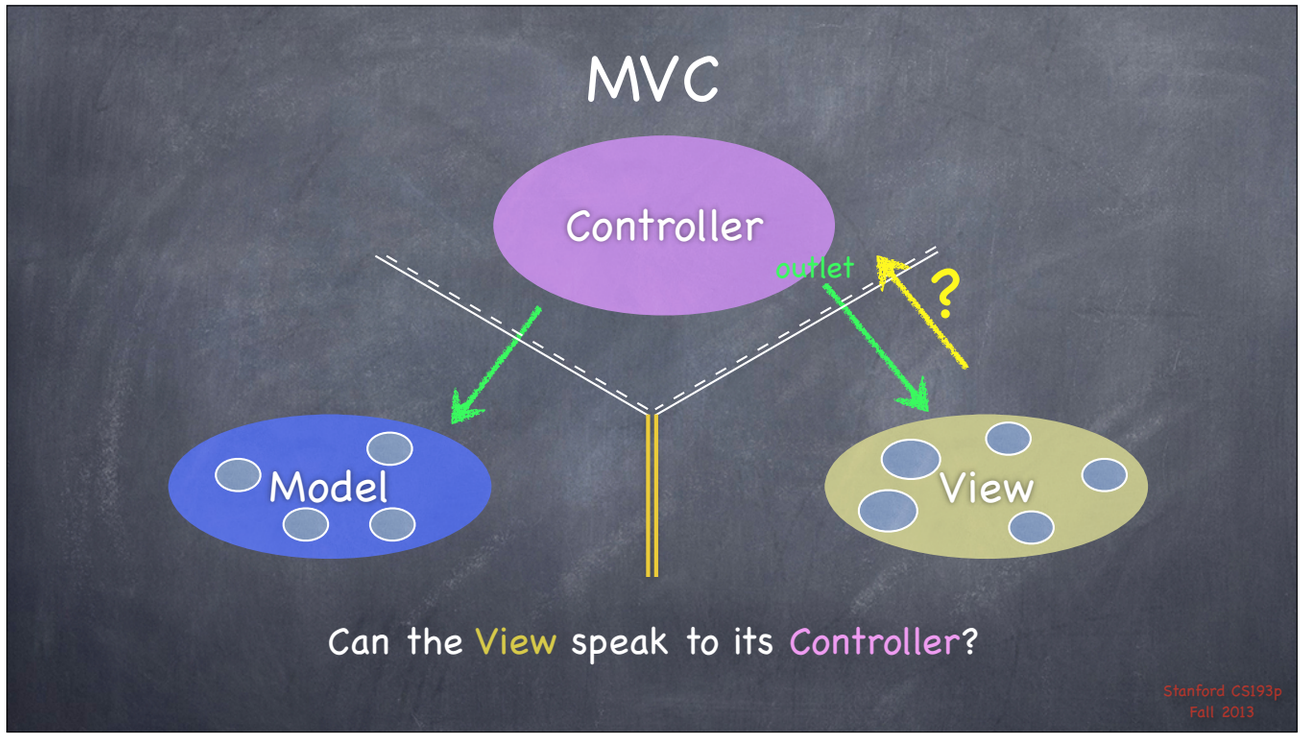


Controllers can also talk directly to their View.

MVC

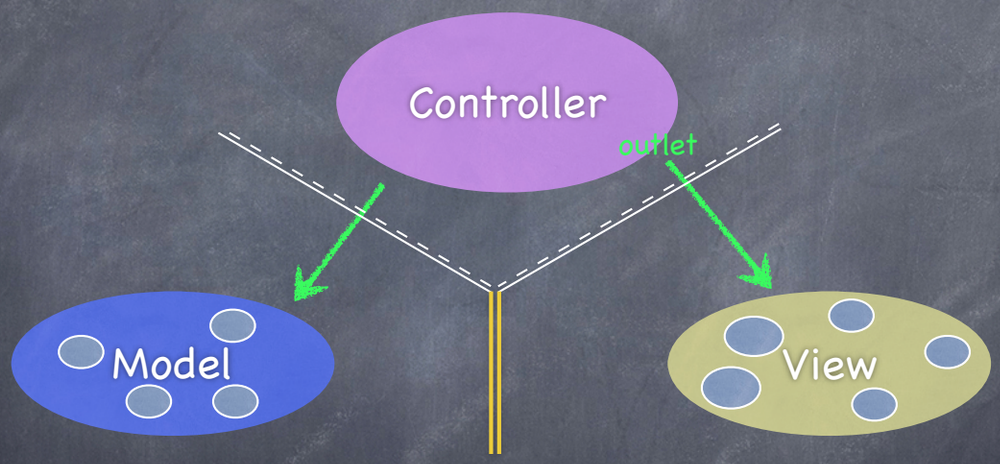


The Model and View should never speak to each other.

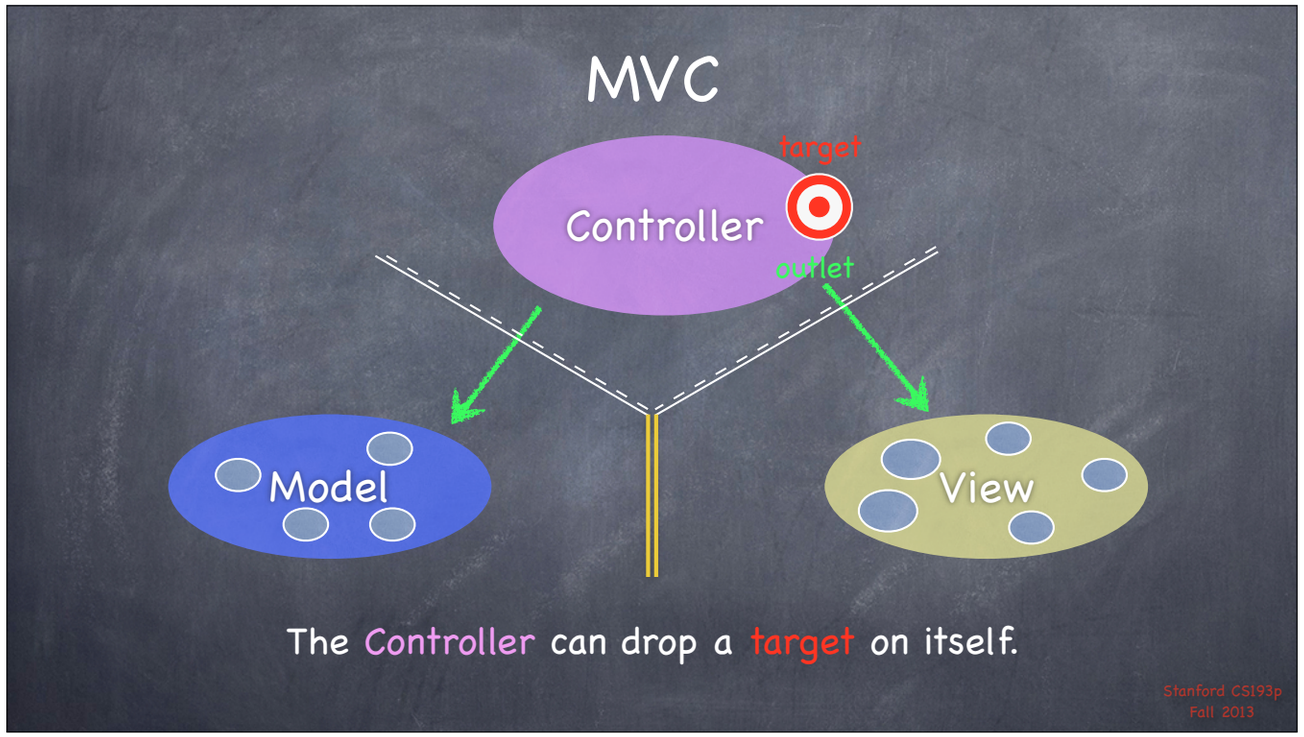


MVC
Controller
outlet
?
Model
View
Can the View speak to its Controller?
Stanford CS193p
Fall 2013

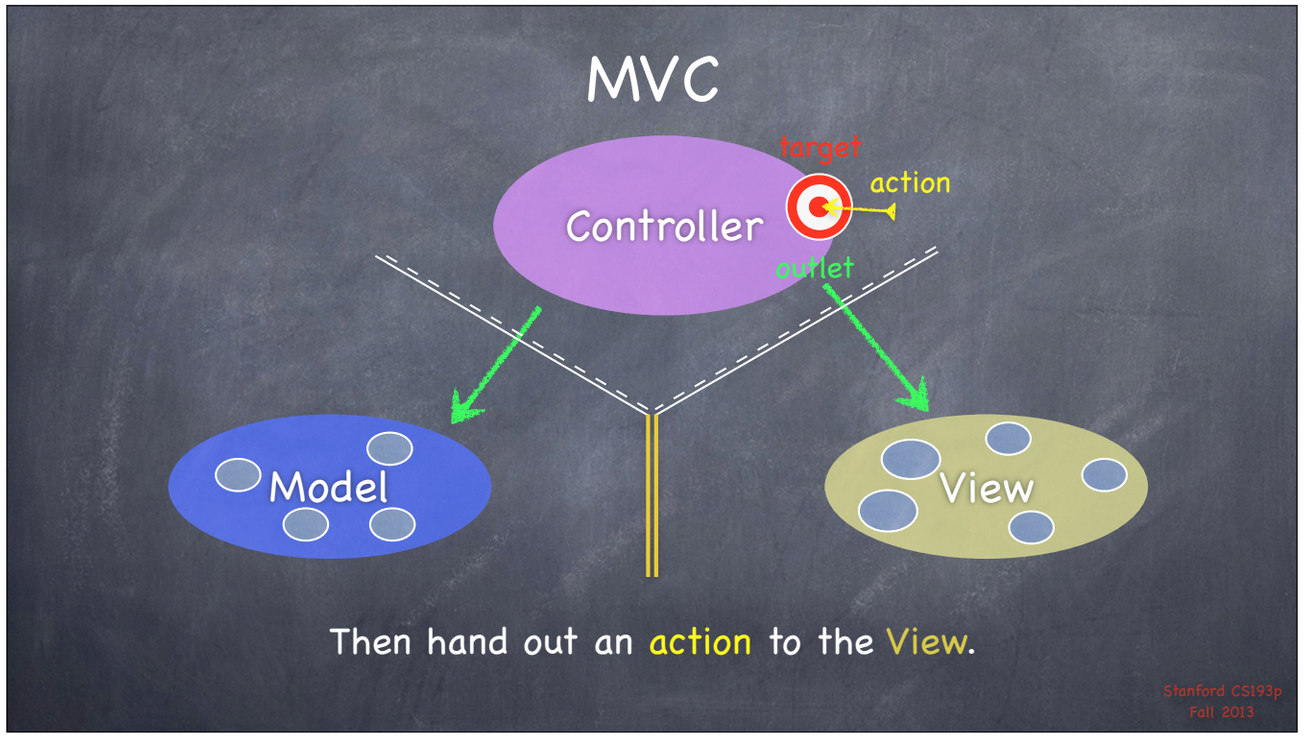
MVC



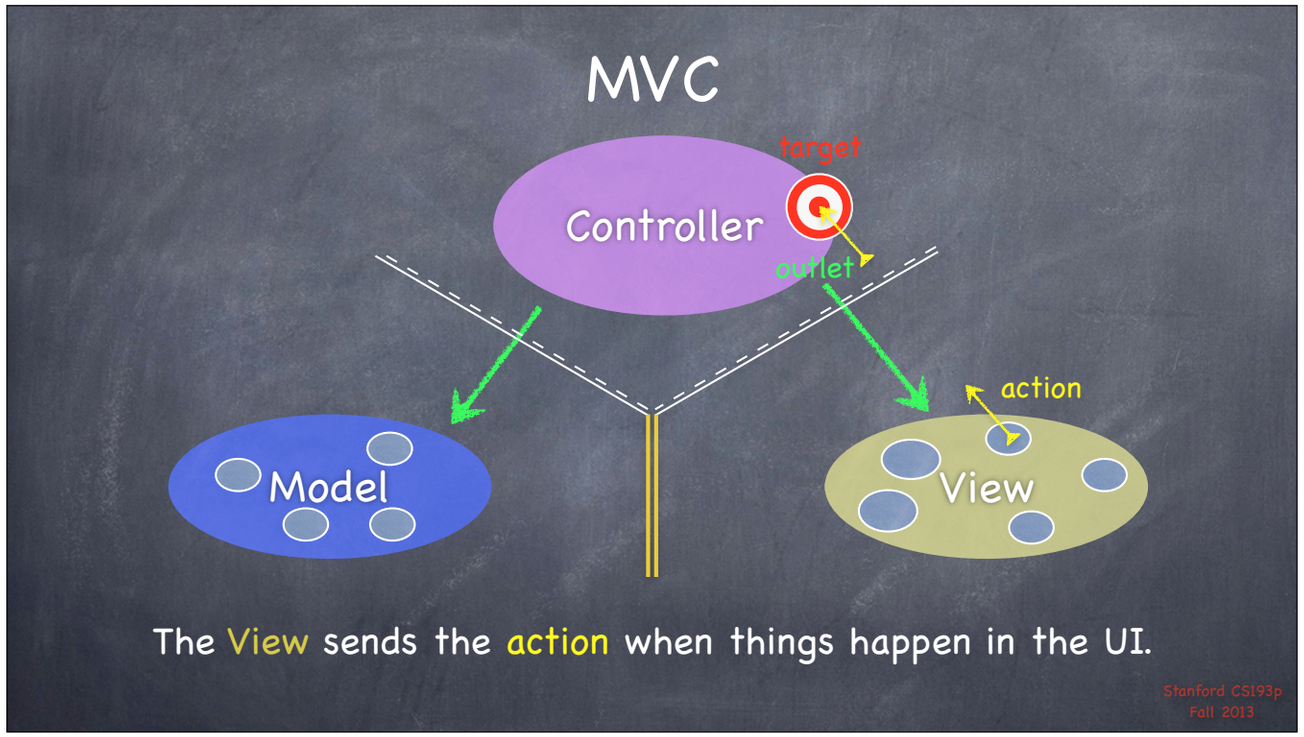
Sort of. Communication is "blind" and structured.



MVC
target
Controller
outlet
Model
View
The Controller can drop a target on itself.
Stanford CS193p
Fall 2013

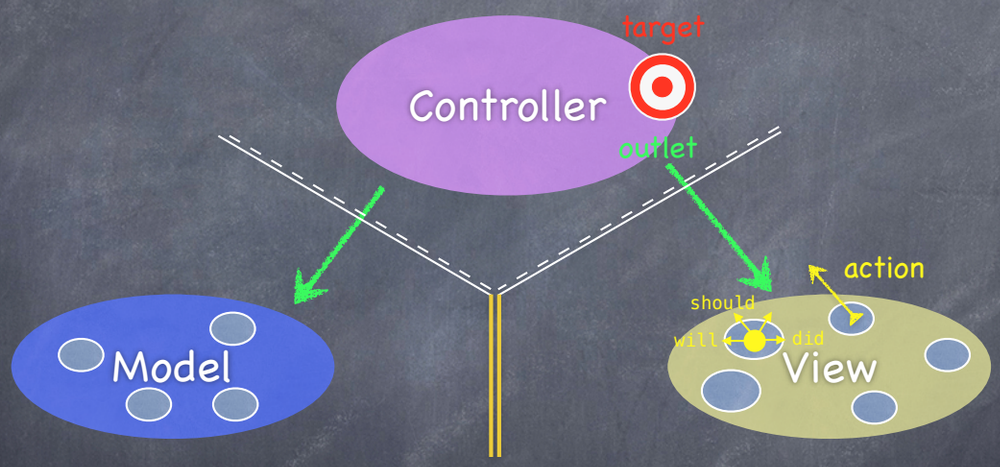


MVC
target
action
Controller
outlet
Model
View
Then hand out an action to the View.
Stanford CS193p
Fall 2013



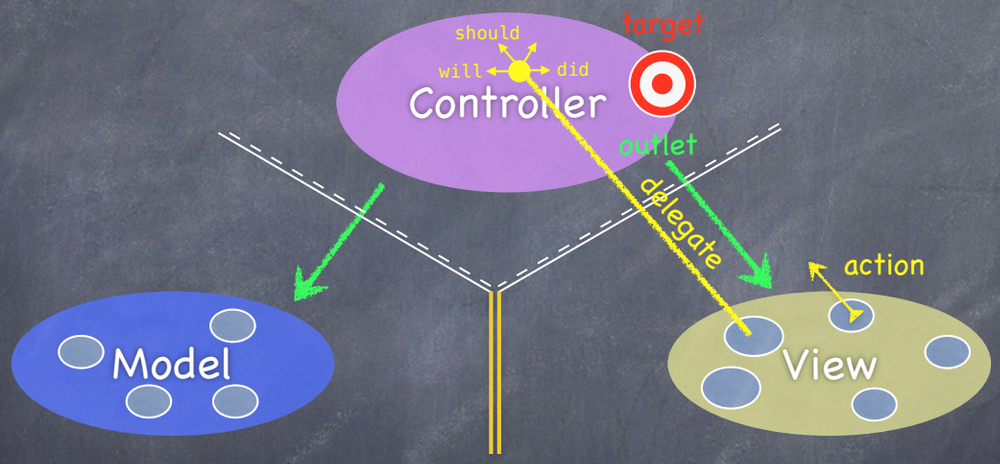
MVC
target
Controller
outlet
action
Model
View
The View sends the action when things happen in the UI.
Stanford CS193p
Fall 2013

MVC



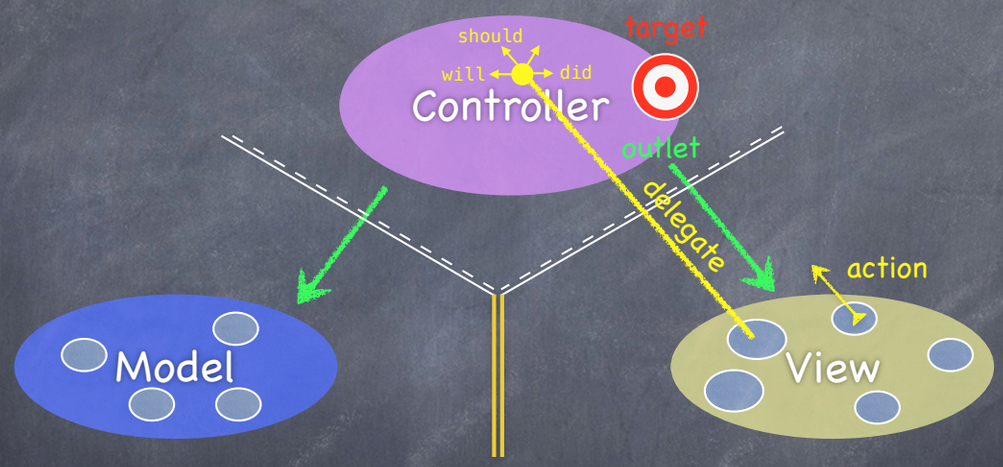
Sometimes the View needs to synchronize with the Controller.

MVC

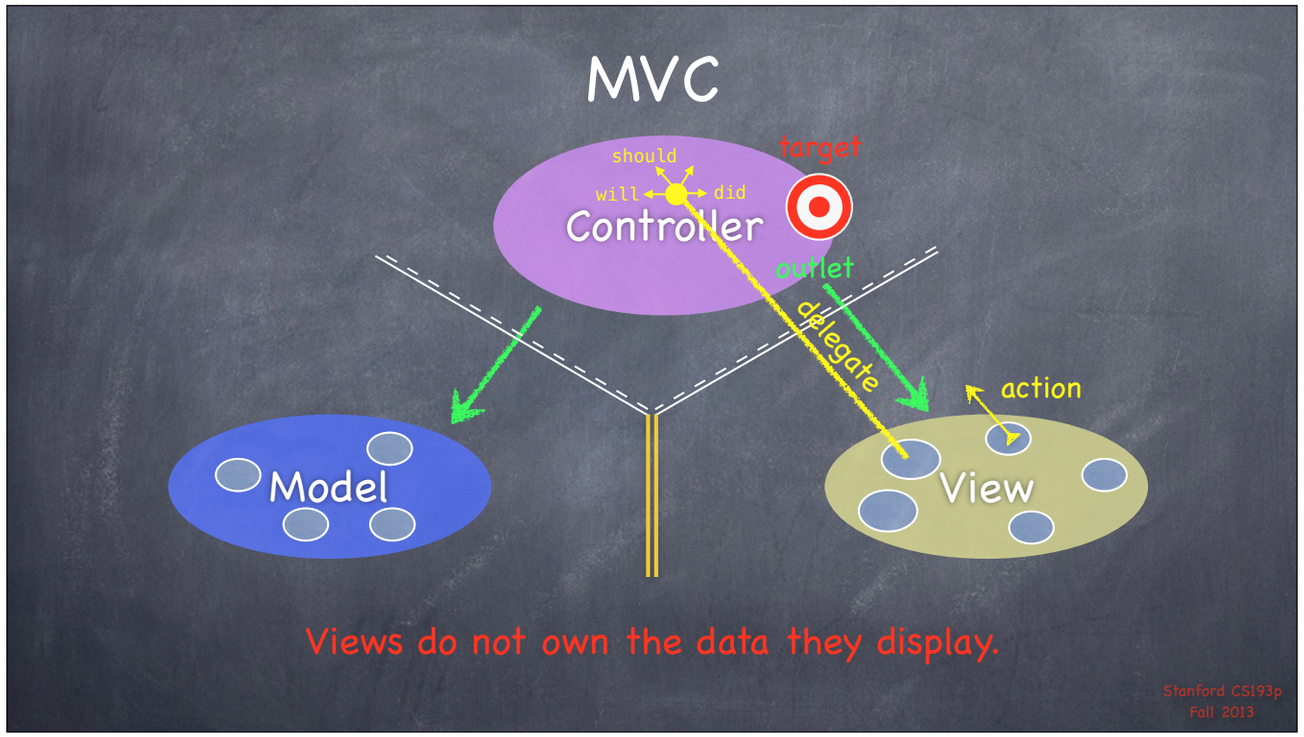


The Controller sets itself as the View's delegate.

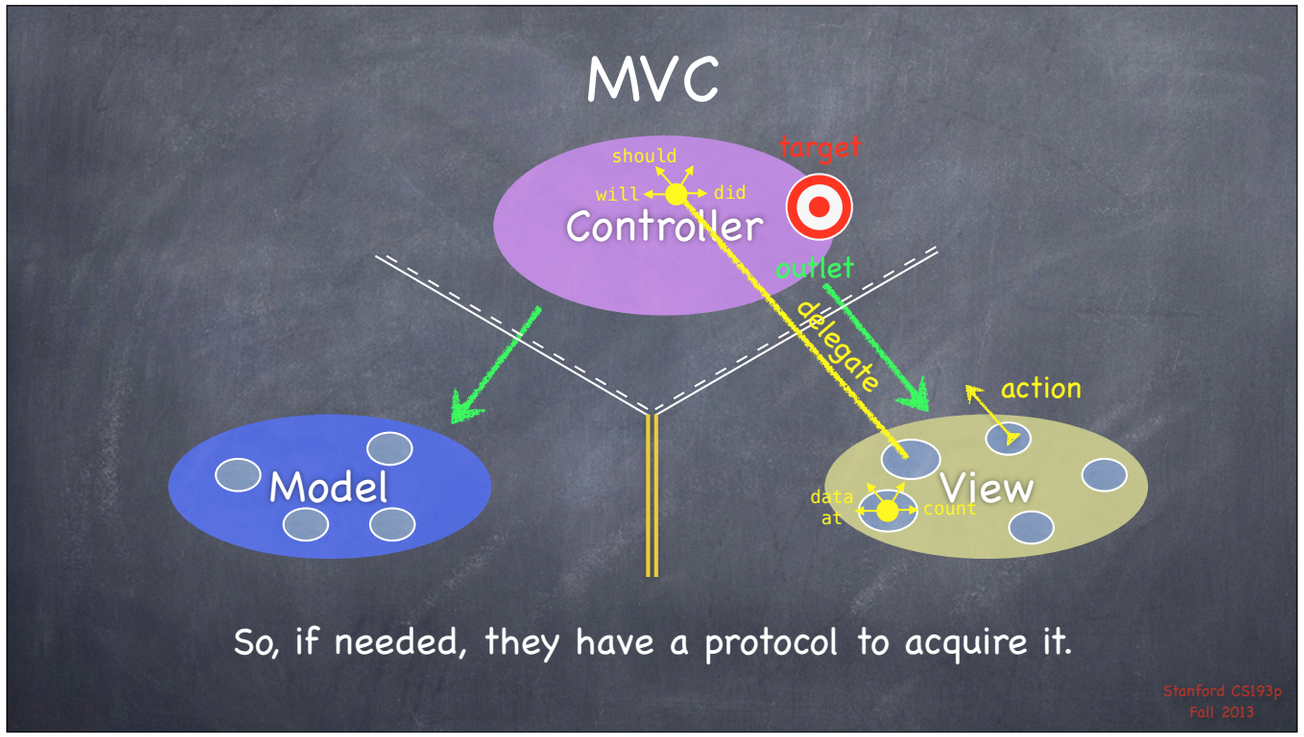
MVC



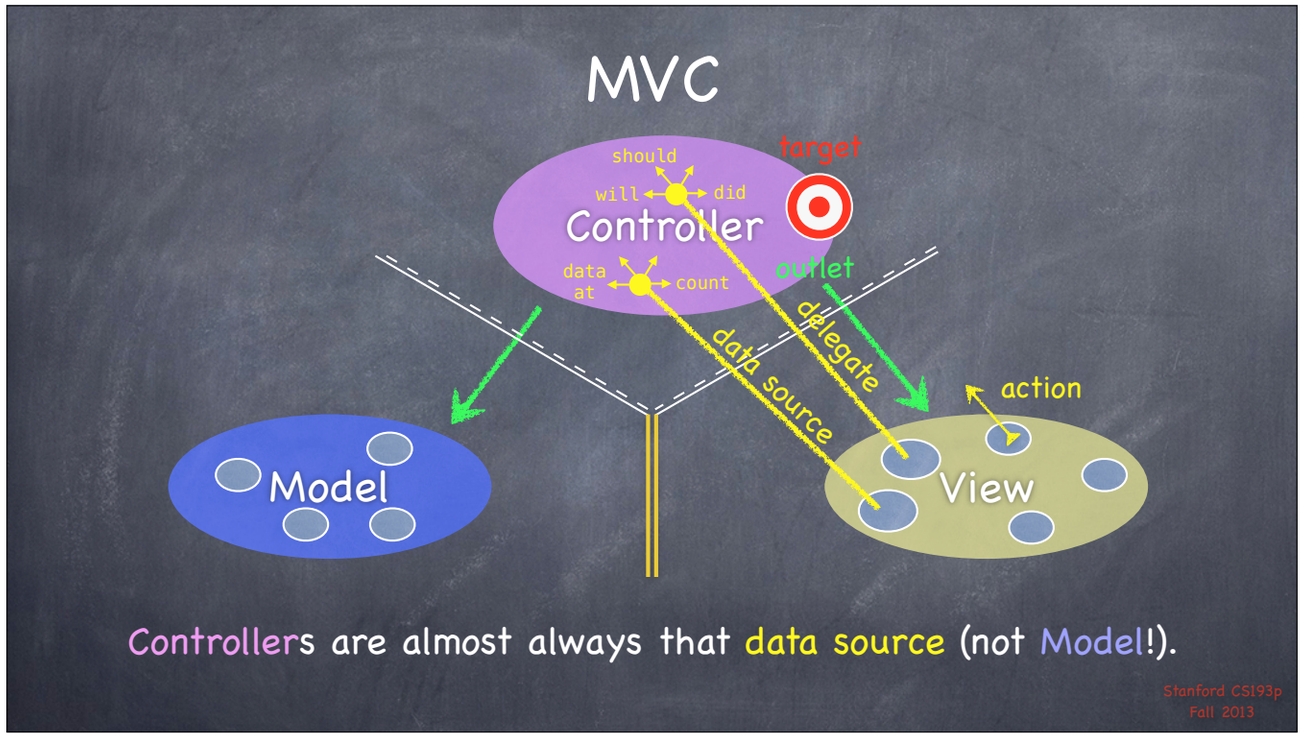
The delegate is set via a protocol (i.e. it's "blind" to class).



MVC
should
will
did
Controller
target
outlet
delegate
action
Model
View
Views do not own the data they display.
Stanford CS193p
Fall 2013



MVC
should
will
did
Controller
target
outlet
delegate
action
Model
data
at
count
View
So, if needed, they have a protocol to acquire it.
Stanford CS193p
Fall 2013



MVC
target
should

Fall 2013

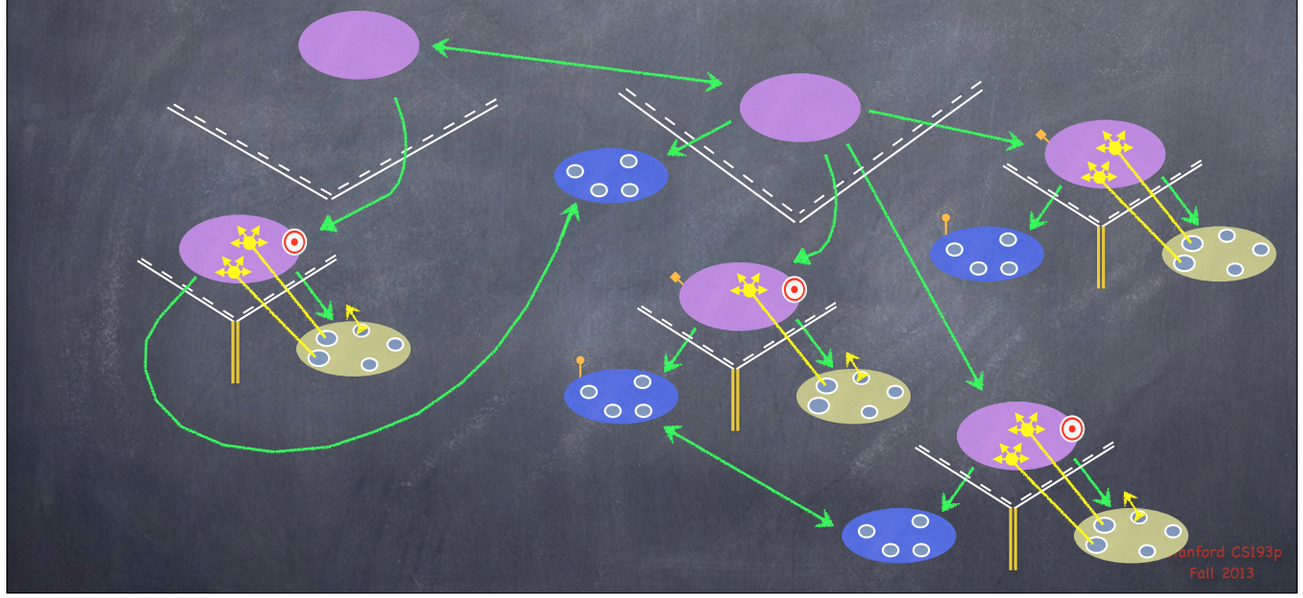
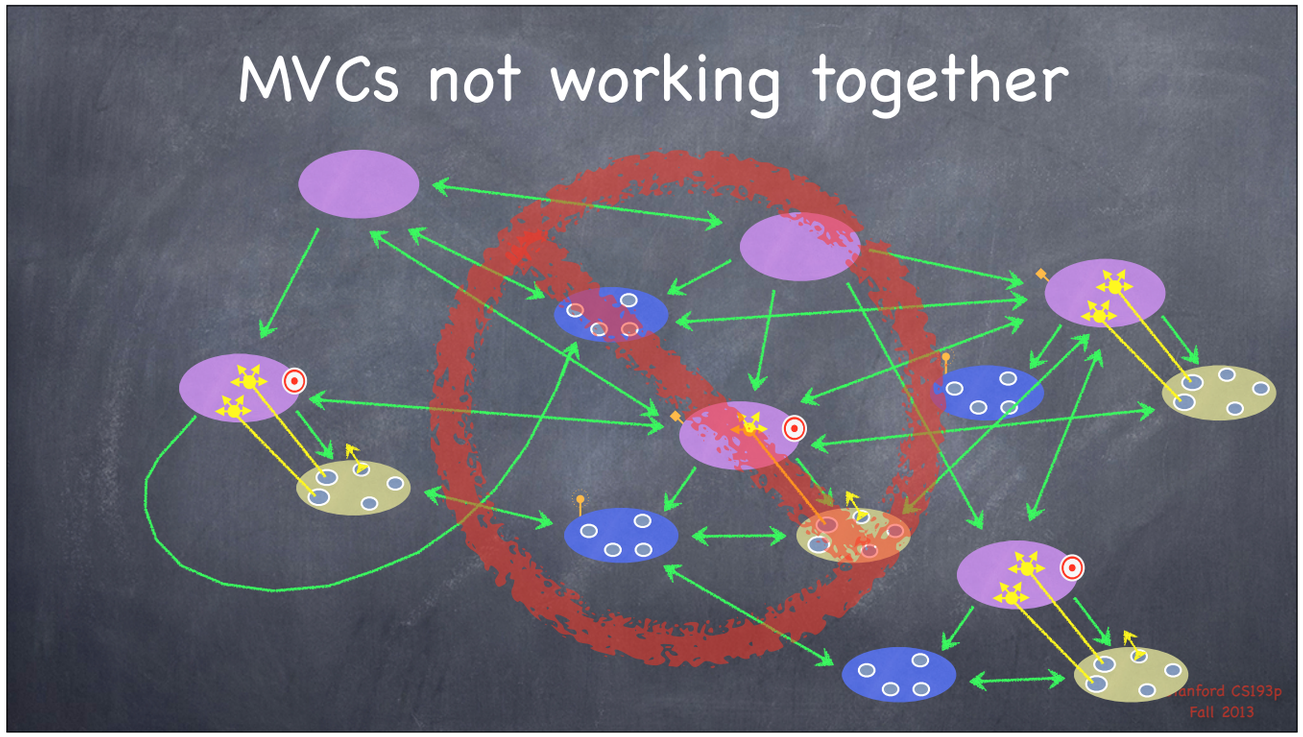
– DEMO (MVC)

MVCs working together

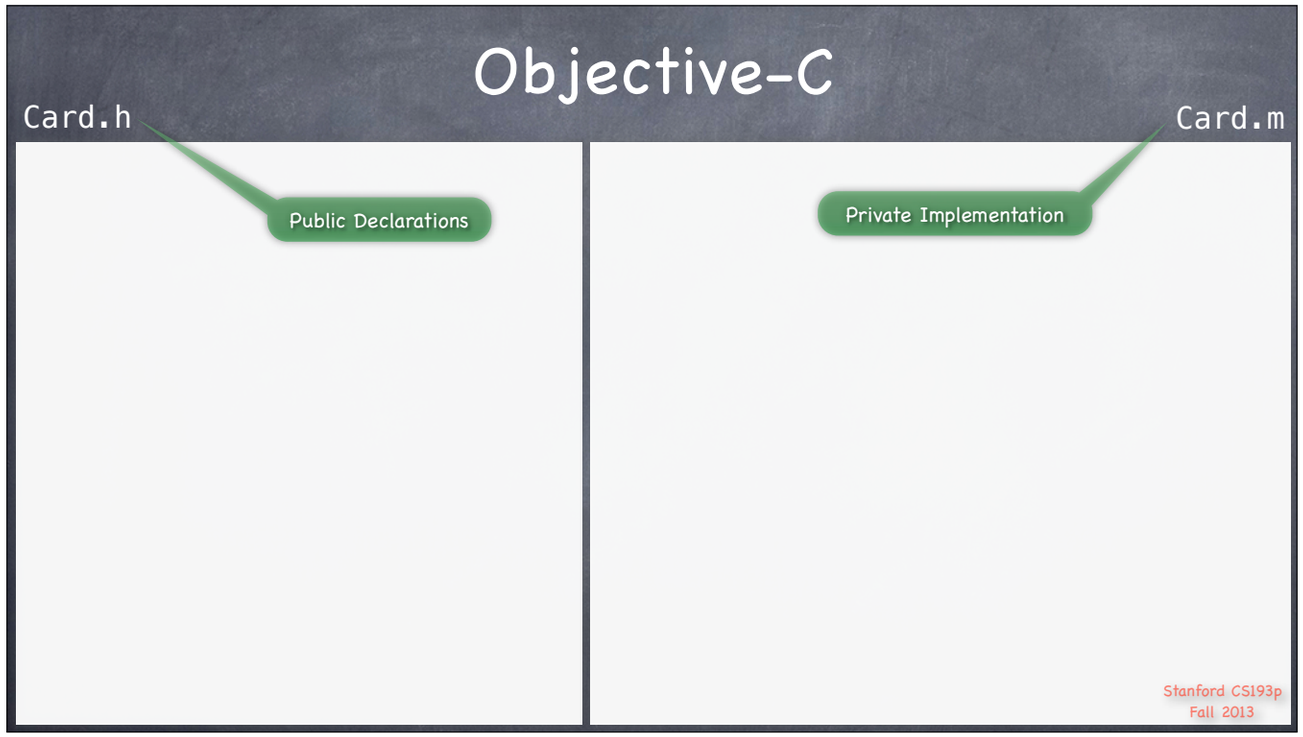


MVCs not working together



Objective-C

- New language to learn!
  - Strict superset of C
  - Adds syntax for classes, methods, etc.
  - A few things to "think differently" about (e.g. properties, dynamic binding)
- Most important concept to understand today: Properties
  - Usually we do not access instance variables directly in Objective-C.
  - Instead, we use "properties."
  - A "property" is just the combination of a getter method and a setter method in a class.
  - The getter (usually) has the name of the property (e.g. "myValue")
  - The setter's name is "set" plus capitalized property name (e.g. "setMyValue:")
  - (To make this look nice, we always use a lowercase letter as the first letter of a property name.)
  - We just call the setter to store the value we want and the getter to get it. Simple.
- This is just your first glimpse of this language!
  - We'll go much more into the details next week.
  - Don't get too freaked out by the syntax at this point.



- Java: 1 .java file

Objective-C

Card.h

Card.m

Its superclass.

```
@interface Card : NSObject
```

The name of this class.

`NSObject` is the root class from which pretty much all iOS classes inherit (including the classes you author yourself).

Don't forget this!

```
@end
```

Objective-C

Card.h

```
@interface Card : NSObject

@end
```

Card.m

```
@implementation Card

@end
```

Note, superclass is not specified here.

Objective-C

Card.h

```
#import <Foundation/NSObject.h>

@interface Card : NSObject

@end
```

Superclass's header file.

Card.m

```
@implementation Card

@end
```

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@end
```

Card.m

```
@implementation Card

@end
```

If the superclass is in iOS itself, we import the entire "framework" that includes the superclass.
In this case, `Foundation`, which contains basic non-UI objects like `NSObject`.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@end
```

Card.m

```
#import "Card.h"

@implementation Card

@end
```

Our own header file must be imported into our implementation file.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@end
```

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

@end
```

Private declarations can go here.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong) NSString *contents;

@end
```

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

@end
```

In iOS, we don't access instance variables directly.
Instead, we use an `@property` which declares two methods: a "setter" and a "getter".
It is with those two methods that the `@property`'s instance variable is accessed
(both publicly and privately).

This particular `@property` is a pointer.
Specifically, a pointer to an object whose class is (or inherits from) `NSString`.

ALL objects live in the heap (i.e. are pointed to) in Objective-C!
Thus you would never have a property of type "`NSString`" (rather, "`NSString *`").

Because this `@property` is in this class's header file, it is public.
Its setter and getter can be called from outside this class's `@implementation` block.

- property = setter + getter
- value is stored in instance variable

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong) NSString *contents;

@end
```

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

@end
```

strong means:
"keep the object that this property points to
in memory until I set this property to nil (zero)
(and it will stay in memory until everyone who has a strong
pointer to it sets their property to nil too)"

weak would mean:
"if no one else has a strong pointer to this object,
then you can throw it out of memory
and set this property to nil
(this can happen at any time)"

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@end
```

nonatomic means:
"access to this property is not thread-safe".
We will always specify this for object pointers in this course.
If you do not, then the compiler will generate locking code that will complicate your code elsewhere.

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

@end
```

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@end
```

This is the `@property` implementation that the compiler generates automatically for you (behind the scenes).
You are welcome to write the setter or getter yourself, but this would only be necessary if you needed to do something in addition to simply setting or getting the value of the property.

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

@synthesize contents = _contents;

- (NSString *)contents
{
    return _contents;
}

- (void)setContents:(NSString *)contents
{
    _contents = contents;
}

@end
```

This `@synthesize` is the line of code that actually creates the backing instance variable that is set and gotten.
Notice that by default the backing variable's name is the same as the property's name but with an underbar in front.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@end
```

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

@end
```

Because the compiler takes care of everything you need to implement a property, it's usually only one line of code (the `@property` declaration) to add one to your class.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@property (nonatomic) BOOL chosen;
@property (nonatomic) BOOL matched;

@end
```

Notice no strong or weak here.
Primitive types are not stored in the heap, so there's no need to specify how the storage for them in the heap is treated.

Let's look at some more properties.
These are not pointers.
They are simple BOOLs.

Properties can be any C type.
That includes int, float, etc., even C structs.

C does not define a "boolean" type.
This BOOL is an Objective-C typedef.
It's values are YES or NO.

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

@end
```

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@property (nonatomic) BOOL chosen;
@property (nonatomic) BOOL matched;

@end
```

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

@synthesize chosen = _chosen;
@synthesize matched = _matched;

- (BOOL)chosen
{
    return _chosen;
}
- (void)setChosen:(BOOL)chosen
{
    _chosen = chosen;
}

- (BOOL)matched
{
    return _matched;
}
- (void)setMatched:(BOOL)matched
{
    _matched = matched;
}

@end
```

Here's what the compiler is doing behind the scenes for these two properties.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@property (nonatomic, getter=isChosen) BOOL chosen;
@property (nonatomic, getter=isMatched) BOOL matched;

@end
```

It is actually possible to change the name of the getter that is generated. The only time you'll ever see that done in this class (or anywhere probably) is boolean getters.

This is done simply to make the code "read" a little bit nicer. You'll see this in action later.

Card.m

```
#import "Card.h"

@interface Card()
@end
@implementation Card

@synthesize chosen = _chosen;
@synthesize matched = _matched;

- (BOOL)isChosen
{
    return _chosen;
}
- (void)setChosen:(BOOL)chosen
{
    _chosen = chosen;
}

- (BOOL)isMatched
{
    return _matched;
}
- (void)setMatched:(BOOL)matched
{
    _matched = matched;
}

@end
```

Note change in getter method.

Note change in getter method.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@property (nonatomic, getter=isChosen) BOOL chosen;
@property (nonatomic, getter=isMatched) BOOL matched;

@end
```

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

@end
```

Remember, unless you need to do something besides setting or getting when a property is being set or gotten, the implementation side of this will all happen automatically for you.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@property (nonatomic, getter=isChosen) BOOL chosen;
@property (nonatomic, getter=isMatched) BOOL matched;

- (int)match:(Card *)card;

@end
```

Enough properties for now.
Let's take a look at defining methods.

Here's the declaration of a public method called `match:` which takes one argument (a pointer to a `Card`) and returns an `integer`.

What makes this method public?
Because we've declared it in the header file.

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

@end
```

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@property (nonatomic, getter=isChosen) BOOL chosen;
@property (nonatomic, getter=isMatched) BOOL matched;

- (int)match:(Card *)card;

@end
```

Here's the declaration of a public method called `match:` which takes one argument (a pointer to a `Card`) and returns an `integer`.

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

- (int)match:(Card *)card
{
    int score = 0;

    return score;
}

@end
```

`match:` is going to return a "score" which says how good a match the passed `card` is to the `Card` that is receiving this message. 0 means "no match", higher numbers mean a better match.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@property (nonatomic, getter=isChosen) BOOL chosen;
@property (nonatomic, getter=isMatched) BOOL matched;

- (int)match:(Card *)card;

@end
```

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

- (int)match:(Card *)card
{
    int score = 0;

    if ([card.contents isEqualToString:self.contents]) {
        score = 1;
    }

    return score;
}

@end
```

There's a lot going on here!
For the first time, we are seeing the "calling" side of properties (and methods).

For this example, we'll return `1` if the passed `card` has the same `contents` as we do or `0` otherwise (you could imagine more complex scoring).

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@property (nonatomic, getter=isChosen) BOOL chosen;
@property (nonatomic, getter=isMatched) BOOL matched;

- (int)match:(Card *)card;

@end
```

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

- (int)match:(Card *)card
{
    int score = 0;

    if ([card.contents isEqualToString:self.contents]) {
        score = 1;
    }

    return score;
}

@end
```

Notice that we are calling the "getter" for the `contents` `@property` (both on our `self` and on the passed `card`). This calling syntax is called "dot notation." It's only for setters and getters.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@property (nonatomic, getter=isChosen) BOOL chosen;
@property (nonatomic, getter=isMatched) BOOL matched;

- (int)match:(Card *)card;

@end
```

Recall that the contents property is an NSString.

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

- (int)match:(Card *)card
{
    int score = 0;

    if ([card.contents isEqualToString:self.contents]) {
        score = 1;
    }

    return score;
}

@end
```

isEqualToString: is an NSString method which takes another NSString as an argument and returns a BOOL (YES if the 2 strings are the same).

Also, we see the "square bracket" notation we use to send a message to an object.
In this case, the message isEqualToString: is being sent to the NSString returned by the contents getter.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@property (nonatomic, getter=isChosen) BOOL chosen;
@property (nonatomic, getter=isMatched) BOOL matched;

- (int)match:(NSArray *)otherCards;

@end
```

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

- (int)match:(NSArray *)otherCards
{
    int score = 0;

    if ([card.contents isEqualToString:self.contents]) {
        score = 1;
    }

    return score;
}

@end
```

We could make `match:` even more powerful by allowing it to match against multiple cards by passing an array of cards using the `NSArray` class in Foundation.

Objective-C

Card.h

```
#import <Foundation/Foundation.h>

@interface Card : NSObject

@property (strong, nonatomic) NSString *contents;

@property (nonatomic, getter=isChosen) BOOL chosen;
@property (nonatomic, getter=isMatched) BOOL matched;

- (int)match:(NSArray *)otherCards;

@end
```

Card.m

```
#import "Card.h"

@interface Card()

@end

@implementation Card

- (int)match:(NSArray *)otherCards
{
    int score = 0;

    for (Card *card in otherCards) {
        if ([card.contents isEqualToString:self.contents]) {
            score = 1;
        }
    }

    return score;
}

@end
```

We'll implement a very simple match scoring system here which is to score 1 point if ANY of the passed `otherCards`' `contents` match the receiving `Card`'s `contents`.
(You could imagine giving more points if multiple cards match.)

Note the `for-in` looping syntax here.
This is called "fast enumeration."
It works on arrays, dictionaries, etc.
